

Padé Unitarizations: A Critical Look

Javier Virto ^{a *}

We use the Linear Sigma Model to test the convergence of different sequences of Padé Approximants when used to unitarize the low energy $\pi\pi$ scattering amplitude. We find that, in this particular case, diagonal sequences reproduce the sigma pole with high accuracy, as opposed to other sequences that have been discussed extensively.

1. INTRODUCTION

One of the most interesting aspects of strong interactions is the enormously rich and complicated hadronic spectrum that arises from such a simple high energy structure. How does exactly this spectrum arise from QCD is a question under study. The understanding of QCD at low energies is basically provided by ChPT [1], the low energy effective theory of QCD, which gives also some insight on the spectrum issue. Although ChPT breaks down in the vicinity of the resonance region, arguments following from unitarity and analyticity are able to extract information on some resonances from the chiral Lagrangian, which contains such information hidden in the values of its low energy constants. One of the most successful of such *unitarization* procedures is the Inverse Amplitude Method (IAM) [2], which is able to extract with acceptable accuracy the lowest lying scalar and vector resonances.

These proceedings are based on the work of Ref. [3], where some of the unitarization techniques are tested by means of the Linear Sigma Model, for which exact information about the sigma resonance is available. We focus on the IAM and also on some sequences of Padé Approximants (PAs) [4].

2. UNITARIZATION OF THE NLSM

In order to determine the scalar meson mass and width up to $\mathcal{O}(g)$, we compute the one-loop

*I would like to thank the organizers of QCD’08 for a very interesting workshop, as well as P.Masjuan and J.J.Sanz-Cillero for a pleasant collaboration. I would also like to acknowledge positive criticism from J.R.Peláez and G.Rios.

sigma correlator,

$$\Delta(s)^{-1} = s - M_\sigma^2 \left[1 + \frac{3g}{16\pi^2} \left(-\frac{13}{3} + \ln \frac{-s}{M_\sigma^2} + 3\rho(s) \ln \left(\frac{\rho(s)+1}{\rho(s)-1} \right) \right) + \mathcal{O}(g^2) \right], \quad (1)$$

where $\rho(s) \equiv \sqrt{1 - 4M_\sigma^2/s}$, and the term $-13/3$ is determined by the renormalization scheme that sets the relation $2gF^2 = M_\sigma^2$ at the one-loop order, with F the pion decay constant. Now it is possible to extract the pole s_p of the propagator up to the considered order in perturbation theory. If one approaches the branch cut from the upper part of the complex s -plane, the pole in the second Riemann sheet is located at

$$s_p = M_\sigma^2 \left[1 + \frac{3g}{16\pi^2} \left(-\frac{13}{3} + \pi\sqrt{3} - i\pi \right) \right] \quad (2)$$

up to corrections of $\mathcal{O}(g^2)$. The pole mass and width, defined from $s_p = (M_p - i\Gamma_p/2)^2$, are then given by

$$\begin{aligned} \frac{M_p^2}{M_\sigma^2} &= 1 + \frac{3g}{16\pi^2} \left(-\frac{13}{3} + \pi\sqrt{3} \right) + \mathcal{O}(g^2) \\ \frac{M_p\Gamma_p}{M_\sigma^2} &= \frac{3g}{16\pi} + \mathcal{O}(g^2). \end{aligned} \quad (3)$$

We now consider the LSM at low energies. The contribution from the sigma exchanges to the renormalized $\mathcal{O}(p^4)$ χ PT couplings gives [1]

$$\begin{aligned} \ell_1^r(\mu) &= \frac{1}{4g} + \frac{1}{96\pi^2} \left[\ln \frac{M_\sigma^2}{\mu^2} - \frac{35}{6} \right] + \mathcal{O}(g), \\ \ell_2^r(\mu) &= \frac{1}{48\pi^2} \left[\ln \frac{M_\sigma^2}{\mu^2} - \frac{11}{6} \right] + \mathcal{O}(g). \end{aligned} \quad (4)$$

The $\pi\pi$ -scattering is determined by the $\pi^+\pi^- \rightarrow \pi^0\pi^0$ amplitude, which is given up to $\mathcal{O}(p^4)$ in the chiral expansion by

$$A(s, t, u) = \frac{s}{F^2} + \frac{2s^2}{F^4} \ell_1^r + \frac{s^2 + (t-u)^2}{2F^4} \ell_2^r \\ + \frac{1}{96\pi^2 F^4} \left[-3s^2 \ln \frac{-s}{\mu^2} - t(t-u) \ln \frac{-t}{\mu^2} \right. \\ \left. - u(u-t) \ln \frac{-u}{\mu^2} + \frac{5s^2}{2} + \frac{7(t-u)^2}{6} \right],$$

where μ refers here to the arbitrary renormalization scale, and the chiral limit has been considered. With this one constructs the definite isospin partial waves, $t_J^I(s)$, with $IJ = 00, 11, 20$, finding the following $\mathcal{O}(p^2)$ amplitudes,

$$t_{0(2)}^0(s) = \frac{s}{16\pi F^2}, \quad t_{1(2)}^1(s) = \frac{s}{96\pi F^2}, \\ t_{0(2)}^2(s) = -\frac{s}{32\pi F^2}, \quad (5)$$

and at $\mathcal{O}(p^4)$,

$$t_{0(4)}^0(s) = t_{0(2)}^0(s) \times \frac{11s}{6M_\sigma^2} \\ \times \left[1 - \frac{g}{264\pi^2} \left(18 \ln \frac{-s}{M_\sigma^2} + 7 \ln \frac{s}{M_\sigma^2} + \frac{193}{3} \right) \right], \\ t_{1(4)}^1(s) = t_{1(2)}^1(s) \times \left(\frac{-s}{M_\sigma^2} \right) \\ \times \left[1 + \frac{g}{48\pi^2} \left(\ln \frac{-s}{M_\sigma^2} - \ln \frac{s}{M_\sigma^2} - \frac{26}{3} \right) \right], \\ t_{0(4)}^2(s) = t_{0(2)}^2(s) \times \left(\frac{-2s}{3M_\sigma^2} \right) \\ \times \left[1 - \frac{g}{24\pi^2} \left(\frac{9}{4} \ln \frac{-s}{M_\sigma^2} + \frac{11}{4} \ln \frac{s}{M_\sigma^2} + \frac{163}{24} \right) \right],$$

up to corrections of $\mathcal{O}(g^2)$. Given the $\mathcal{O}(p^2)$ and $\mathcal{O}(p^4)$ χ PT amplitudes from Eqs. (5)–(6), it is then possible to extract the poles of the corresponding $t(s)_{\text{IAM}}$ for the LSM, satisfying $t(s)_{(4)}/t(s)_{(2)} = 1$ at $s = s_p^{IJ}$:

$$s_p^{00} = \frac{6}{11} M_\sigma^2 \left[1 + \frac{g}{264\pi^2} \left(\frac{193}{3} + 25 \ln \frac{6}{11} - 18i\pi \right) \right],$$

$$s_p^{11} = -M_\sigma^2 \left[1 + \frac{g}{48\pi^2} \left(\frac{26}{3} + i\pi \right) \right],$$

$$s_p^{20} = -\frac{3}{2} M_\sigma^2 \left[1 + \frac{g}{24\pi^2} \left(\frac{163}{24} + 5 \ln \frac{3}{2} + \frac{11i\pi}{4} \right) \right].$$

These are the poles that appear in the unphysical Riemann sheet as one approaches from upper half of the first Riemann sheet. There is also a conjugate pole at s_p^* if one approaches the real s -axis from below.

The first thing to be noticed is that poles appear in the $IJ = 11$ and 20 channels even for small values of g , contrary to what one expects in the LSM, where no meson with these quantum numbers exists. Furthermore, these “states” are not resonances, as they are located on the left-hand side of the complex s -plane, out of the physical Riemann sheet, and carrying a negative squared mass.

As for the $IJ = 00$ channel, one finds a resonance with pole mass and width,

$$\frac{M_p^2}{M_\sigma^2} = \frac{6}{11} \left[1 + \frac{g}{16\pi^2} \left(\frac{50}{33} \ln \frac{6}{11} + \frac{386}{99} \right) \right], \\ \frac{M_p \Gamma_p}{M_\sigma^2} = \frac{24}{121} \cdot \frac{3g}{16\pi} + \mathcal{O}(g^2). \quad (7)$$

The IAM predictions for M_p^2 and $M_p \Gamma_p$ result, respectively, 40% and 80% smaller than the original ones in the LSM, computed in Eq. (3). Therefore, this provides an example of a situation in which this particular method cannot reproduce the hadronic properties of the theory from its effective low-energy description.

3. HIGHER ORDER PA's

Now we consider higher order PAs. In order to be able to handle the amplitude at higher orders, we will consider the $\pi\pi$ scattering at tree-level. This is equivalent to working in the limit $g \ll 1$ and keeping just the first non-trivial contribution in the g expansion. At low energies the amplitude becomes

$$A(s, t, u) = \frac{s}{F^2} \left[1 + \frac{s}{M_\sigma^2} + \frac{s^2}{M_\sigma^4} + \dots \right], \quad (8)$$

Figure 1. Position of the nearest pole to M_σ^2 for the first PAs of the form $[1/N]$ with N odd (for even N all the poles are complex).

and the partial waves are given by,

$$\begin{aligned} t_0^0(s) &= \frac{s}{16\pi F^2} \left[1 + \frac{11s}{6M_\sigma^2} + \frac{15s^2}{12M_\sigma^4} + \dots \right], \\ t_1^1(s) &= \frac{s}{96\pi F^2} \left[1 - \frac{s}{M_\sigma^2} + \frac{9s^2}{10M_\sigma^4} + \dots \right], \\ t_0^2(s) &= -\frac{s}{32\pi F^2} \left[1 - \frac{2s}{3M_\sigma^2} + \frac{s^2}{2M_\sigma^4} + \dots \right]. \end{aligned} \quad (9)$$

In this section we compare the $[1/N]$ and $[N/N]$ sequences for the study of the $\pi\pi$ partial wave scattering amplitudes. We shall focus on the $IJ = 00$ partial wave, but analogous results are found for the other channels. Former works pointed out that the PAs and other unitarizations fail to incorporate the crossed channel resonance exchanges. Nonetheless, we will see that as N grows, the poles of the sequence $[N/N]$ actually tend to mimic not only the s -channel poles but also the left-hand cut contribution from diagrams with resonances in the t and u channels.

We begin with the sequences of the type $[1, N]$. Our results are summarized in Figs. 1 and 2: No convergence is found with this sequence. In the case of N odd, Fig. 1 shows that the P_N^1 pole closest to M_σ^2 does not approach this value even for very large N , always remaining a 30% below. The analytical structure of the original amplitude (s -channel sigma pole plus left-hand cut) is never recovered since the $[1/N]$ PAs always set the poles in the circular pattern shown in Fig. 2. This suggests that the use of further $[1/N]$ approximants

Figure 2. Poles of the P_{61}^1 in the complex plane.

to extend the IAM is not the optimal way to proceed, even if we had an accurate knowledge of the low-energy expansion up to very high orders.

Alternatively, the use of sequences such as $[N+K/N]$ (e.g. $[N-2/N]$, $[N-1/N]$, $[N/N] \dots$) seems to be a better strategy. In the following we analyze the sequence $[N/N]$, as it ensures the appropriate behavior at high energies, $|t(s)| < 1$. Nevertheless, similar results have been generally found for the $[N+K/N]$ PAs with $K \neq 0$. The P_N^N pole closest to M_σ^2 is shown in Fig. 3. One finds a quick convergence of the sequence: P_1^1 reproduces the sigma pole a 40% off but P_2^2 disagrees by less than 1%, P_3^3 by less than 0.1%, etc. Notice that already P_2^2 provides a much better description than P_{61}^1 , although one includes far more low-energy information in the latter. All this points out the sizable discrepancy of the first element of the sequence (P_1^1) with respect to the original amplitude. It also indicates that the $[1/N]$ PAs do not produce a serious improvement. On the contrary, the $[N/N]$ sequences provide a more efficient strategy with a quick convergence.

Likewise, Fig. 2 shows how the $[1/N]$ PAs are unable to recover the analytical structure of the original amplitude, whereas the $[N/N]$ sequence, besides providing the isolated pole of the sigma, tends to reproduce the left-hand cut as N increases. The poles of P_{20}^{20} are plotted in Fig. 4. Although a PA is a rational function without cuts, these are mimicked by placing poles where the cuts should lie. The P_{20}^{20} has one isolated pole near M_σ^2 (with an accuracy of 10^{-30}) and nineteen poles over the real axis at $s_p < -M_\sigma^2$, i.e. on the left-hand cut of the original function. As

Figure 3. Location of the closest pole to M_σ^2 for the first $[N/N]$ PAs.

N is increased, the number of poles lying on the branch cut increases too.

As an amusement, we have also probed the PA sequence $[N/1]$ which has the same number of inputs as the $[1/N]$ has for a given N . In this new case we have found convergence in both LSM and the resonance model presented in the following section but slower than the $[N/N]$. For instance, the prediction for the M_σ^2 for the first P_1^N are $\frac{s_p}{M_\sigma^2} = 0.55, 1.47, 0.73, 1.27, 0.81 \dots$ A criticism that can be done to this sequence is its lack of unitarity, in contrast to the other studied sequences.

4. CONCLUSIONS

The conclusion seems to be two-fold. First, the LSM features a low energy behavior for which the IAM does not provide a good approximation, at least in what concerns the sigma pole. Second, while some PAs converge amazingly well, even beyond expectation (there are in these cases no theorems ensuring convergence), as for example the diagonal sequences $[N, N]$, some other sequences such as $[1, N]$ show a particularly poor convergence. In addition, the convergent sequences display an analytic structure that mimics perfectly poles and cuts.

Concerning the first point, some explanation has been provided by some of the authors of [2]. They argue that the IAM is a good approximation in strongly interacting regimes where unitarity violations are relevant, while in the case of a weakly interacting set-up as the one described here, in the limit $g \ll 1$ the chiral expansion

Figure 4. Poles of P_{20}^{20} .

breaks down. This is due to the fact that in this limit the contact $\mathcal{O}(p^4)$ terms are as important as the loop contributions. The IAM would behave properly for values of the LECS of order 10^{-3} , as is the case in QCD. Moreover, they argue that in the weakly interacting limit the sigma resonance is almost decoupled, and thus the fact that the IAM can pin it down with a precision of about 40% is remarkable. A more careful investigation of how the approximations involved in the derivation of the IAM, break down in the LSM, would help to clarify this issue.
